## Digest functions

- ▷ Give a fixed-length value from a variable-length text
  - ♦ Sort of text “fingerprint”
- ▷ Produce very different values for similar texts
  - ♦ Cryptographic one-way hash functions
- ▷ Relevant properties:
  - ♦ Preimage resistance
    - Given a digest, it is infeasible to find an original text producing it
  - ♦ 2<sup>nd</sup>-preimage resistance
    - Given a text, it is infeasible to find another one with the same digest
  - ♦ Collision resistance
    - It is infeasible to find any two texts with the same digest
    - ♦ Birthday paradox

## Digest functions

### Approaches

- ♦ Collision-resistant, one-way compression functions
- ♦ Merkle-Damgård construction
  - Iterative compression
  - Length padding (1, followed by zeros, followed by length)

### Most common algorithms

- ♦ MD5 (128 bits)
  - No longer secure! It's easy to find collisions!
- ♦ SHA-1 (Secure Hash Algorithm, 160 bits)
  - Also no longer secure ... (collisions found in 2017)
- ♦ Other
  - RIPEM
  - SHA-2, aka SHA-256/SHA-512
  - SHA-3, etc.

## Rainbow tables

### We can invert a digest function with a table

- ♦ For all possible input, we compute and store the digest
- ♦ But the table size is given by the digest length
  - Not usually applicable

### Solution: rainbow tables

- ♦ Trade space with time
- ♦ Store only part of the outputs
  - For direct matching
- ♦ Find for more matches using computation

## Rainbow tables

- ▷ They are based on a reverse function **R**
  - Which is not the inverse of **H**
  - The goal of **R** is to produce a new input given a hashing result

- ▷ R functions are likely to produce collisions
  - But we can use many different R functions
  - Collisions scan still occur
    - But will not create a problem unless occurring at the exact same column
    - And that case can be identified (and discarded) by identical outputs
- ▷ A table with  $m$   $k$ -length rows can invert  $k \times m$  hashes
  - At most
  - Only  $I_0$  and  $I_k$  is stored per row

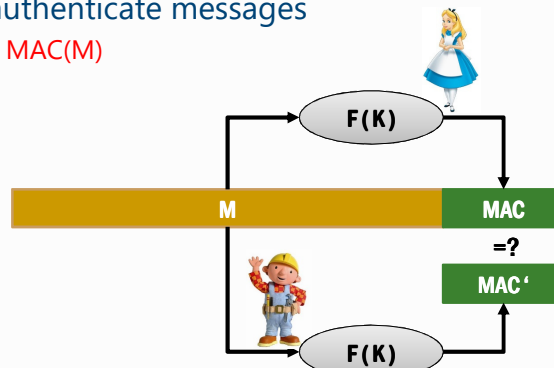

## Rainbow tables: exploitation

- ▷ A set of  $m$  random inputs is generated
  - $I_0 = \{I_{0,1}, \dots, I_{0,m}\}$
- ▷ A set of  $m$   $k$ -length chain outputs is computed
  - $I_k = \{I_{k,1}, \dots, I_{k,m}\}$
- ▷ Given a target  $o$ 
  - Look for  $R(o)$  in  $I_k$
  - If found in row  $r$ , compute chain from  $I_{0,r}$ 
    - until finding  $i$  such that  $H(i) = o$
  - If not found, compute  $o_r$  from  $o$  using **H** and **R** for each row  $r$ 
    - and see if  $o_r = I_{k,r}$
    - **H** and **R** are applied 1 to  $k$  times, using different R functions

## Message Authentication Codes (MAC)

- ▷ Hash, or digest, computed with a key
  - ♦ Only key holders can generate and validate the MAC
- ▷ Used to authenticate messages
  - ♦  $M' = M \mid \text{MAC}(M)$

## Message Authentication Codes (MAC): Approaches

- ▷ Encryption of an ordinary digest
  - ♦ Using, for instance, a symmetric block cipher
- ▷ Using encryption with feedback & error propagation
  - ♦ ANSI X9.9 (or DES-MAC) with DES CBC (64 bits)
  - ♦ CBC-MAC

## Message Authentication Codes (MAC): Approaches

### ▷ Adding a key to the hashed data

- ♦ Keyed-MD5 (128 bits)
    - $\text{MD5}(K, \text{keyfill}, \text{text}, K, \text{MD5fill})$
  - ♦ HMAC (Hashed-based MAC)
    - Generic construction, uses a hash function  $H$
    - Output length depends on  $H$
    - HMAC-MD5, HMAC-SHA, etc.
- $H(K, \text{opad}, H(K, \text{ipad}, \text{text}))$
- $\text{ipad} = 0x36$  B times
- $\text{opad} = 0x5C$  B times

## Authenticated encryption

### ▷ Encryption mixed with integrity control

- ♦ Error propagation
- ♦ Authentication tags

### ▷ Examples

- ♦ GCM (Galois/Counter Mode)
- ♦ CCM (Counter with CBC-MAC)

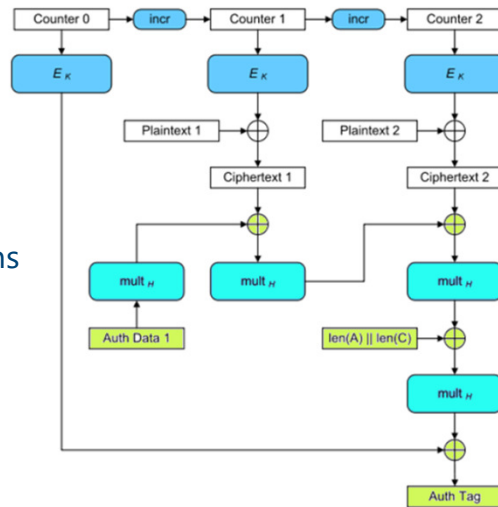

# GCM

## CTR mode encryption

## Successive multiplications for integrity control

- Multiplications in  $GF(2^n)$
- $H = E_K(0)$

# Encryption + authentication

## Encrypt-then-MAC

- MAC is computed from cryptogram
- Should use two different keys
- IPSec uses it

## Encrypt-and-MAC

- MAC is computed from plaintext
- MAC is not encrypted
- SSH uses it

## MAC-then-Encrypt

- MAC is computed from plaintext
- MAC is encrypted
- TLS uses it
